62 Foreword

63 ISO (the International Organization for Standardization) and IEC (the International Electrotechnical
64 Commission) form the specialized system for worldwide standardization. National bodies that are members
65 of ISO or IEC participate in the development of International Standards through technical committees
66 established by the respective organization to deal with particular fields of technical activity. ISO and IEC
67 technical committees collaborate in fields of mutual interest. Other international organizations,
68 governmental and non-governmental, in liaison with ISO and IEC, also take part in the work. In the field of
69 information technology, ISO and IEC have established a joint technical committee, ISO/IEC JTC 1.

70 International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

71 The main task of the joint technical committee is to prepare International Standards. Draft International
72 Standards adopted by the joint technical committee are circulated to national bodies for voting. Publication
73 as an International Standard requires approval by at least 75 % of the national bodies casting a vote.

74 Attention is drawn to the possibility that some of the elements of this document may be the subject of
75 patent rights. ISO and IEC shall not be held responsible for identifying any or all such patent rights.

76 ISO/IEC 19763-1 was prepared by Joint Technical Committee ISO/IEC JTC 1, *Information Technology*,
77 Subcommittee SC 32, *Data management and Interchange*.

78 ISO/IEC 19763 consists of the following parts, under the general title *Information technology — Metamodel
79 framework for interoperability (MFI)*:

80 *Part 1: Framework*

81 *Part 3: Metamodel for ontology registration*

82 *Part 5: Metamodel for process model registration*

83 *Part 6: Registry summary*

84 *Part 7: Metamodel for service registration*

85 *Part 8: Metamodel for role and goal registration*

86 *Part 9: On demand model selection based on RGPS [Technical Report]*

87 *Part 10: Core model and basic mapping*

88 *Part 12: Metamodel for information model registration*

89 *Part 13: Metamodel for forms registration*

90 **Introduction**

91 Due to the proliferation of internet-enabled communication aided by mobile devices, social network
92 systems and cloud computing, both the efficient and effective sharing of information and the handling of
93 business transactions across countries and cultures has become easier.

94 In the private sector the handling of these business transactions using Electronic Data Interchange (EDI)
95 has been common for a long time. Companies hold large quantities of structured, semi-structured and
96 unstructured data – the “Big Data” explosion. It is in their interest to make effective use of this data to
97 extract business intelligence and knowledge.

98 In the public sector, governments in many countries and territories are working on the establishment of
99 new schemes that enable interoperation and collaboration among different departments or agencies,
100 materialising the semantic interoperability of data and surmounting border and/or language differences. At
101 the same time, many governments and agencies are attempting to make their data available to their
102 citizens over the internet, the “Open Data” initiatives. These “Open Data” initiatives could be the driver for
103 similar innovations in the private sector. One of the issues for users is to access the various sets of open
104 data easily and integrate them for analysis so as to create new value through added information or
105 knowledge.

106 These trends have produced new needs for standards that enable effective information sharing in both
107 private and public sectors.

108 One of the key enablers of this sharing of the information that is used by different communities through the
109 interoperability of systems is a registry, or a network of inter-connected registries, that provides for the
110 discovery and sharing of meta-information, such as metadata or models. The Metamodel Framework for
111 Interoperability (MFI) provides the specifications for such registries.

112 The MFI specifications can be considered as an extension of those for a Metadata Registry (MDR) as
113 defined in ISO/IEC 11179-3 because MFI and MDR share the same registration mechanism and
114 procedures. In 2010 a special study project was initiated to consider the harmonisation of MDR and MFI
115 and a key recommendation of that study project was that the common facilities should be identified and
116 used for both MDR and MFI. It is anticipated that MDR and MFI could be more closely related and
117 integrated, leading to benefits for the users who need more effective sharing of information and models, or
118 more sophisticated interoperation of systems.

119 This new edition of Part 1 has been developed to provide a clear overview of MFI and to illustrate the
120 overall architecture of the MFI family of standards to reflect the major changes described above.

121 Information technology – Metamodel framework for 122 interoperability (MFI) – Part 1: Framework

123 1 Scope

124 1.1 Inclusions

125 This standard is a part of the ISO/IEC19763 (Metamodel framework for interoperability) (MFI) family of
126 standards. As the first part of MFI, this standard provides an overview of the whole of MFI. In particular, the
127 purpose, the underlying concepts, the overall architecture and the requirements for the development of
128 other standards within the MFI family are described.

129 MFI provides a set of normative metamodels to enable the registration of many different types of model.
130 Each of these metamodels is expressed as a UML Class Diagram.

131 MFI is evolving. Currently, in addition to this part, the MFI family comprises:

- 132 • A core model and facilities for the basic mapping of models (Part 10)
- 133 • A metamodel for ontology registration (Part 3)
- 134 • A metamodel for process model registration (Part 5)
- 135 • A metamodel for service registration (Part 7)
- 136 • A metamodel for role and goal registration (Part 8)
- 137 • A Technical Report describing on demand model selection based on RGPS (Part 9)
- 138 • A metamodel for information model registration (Part 12)
- 139 • A metamodel for forms registration (Part 13)
- 140 • A metamodel for a registry summary (Part 6)

141 These parts are described in more detail in Annex A.

142 1.2 Exclusions

143 The MFI does not specify any physical structure of the registry where model information is to be recorded.
144 MFI metamodels define standard views as models to be used in the registering of model instances in a
145 model registry while actual instance documents could be stored in a model repository.

146

147 **2 Conformance**

148 ISO/IEC 19763-1 specifies no conformance requirements. Other parts of the ISO/IEC 19763 family of
149 standards specify their own conformance requirements as appropriate.

150

151 **3 Normative references**

152 The following referenced documents are indispensable for the application of this document. For dated
153 references only the edition cited applies. For undated references the latest edition of the referenced
154 document (including any amendments) applies.

155 ISO/IEC 11179-3, Information technology – Metadata registries (MDR) – Part 3: Registry metamodel and
156 basic attributes

157 ISO/IEC 11179-6, Information technology – Metadata registries (MDR) – Part 6: Registration

159 (OMG UML) -- Part 1: Infrastructure

160 ISO/IEC 19505-2:2012, Information technology -- Object Management Group Unified Modeling Language
161 (OMG UML) -- Part 2: Superstructure

162

163 **4 Terms, definitions and abbreviated terms**

164 **4.1 Terms and definitions**

165 For the purposes of this document, the following terms and definitions apply.

166 **4.1.1**

167 **concept**

168 unit of knowledge created by a unique combination of characteristics

169 NOTE Concepts are not necessarily bound to particular languages. They are, however, influenced by the social or
170 cultural background which often leads to different categorizations.

171 [ISO 1087-1:2000, 3.2.1]

172 **4.1.2**

173 **cloud computing**

174 paradigm for enabling network access to a scalable and elastic pool of shareable physical or virtual
175 resources with self-service provisioning and administration on-demand

176 [ISO/IEC DIS 17788, 3.2.4]

177 NOTE Examples of resources include servers, operating systems, networks, software, applications, and storage
178 equipment.

- 179 **4.1.3**
180 **framework**
181 logical structure for classifying and organizing complex information
- 182 [ISO/TS 27790:2009, 3.27]
- 183 NOTE In MFI the framework is used to represent the architectural view of a set of metamodels for registration.
- 184 **4.1.4**
185 **information model**
186 graphical and textual representation of entities and the relationships between them
- 187 NOTE May also be known as a data model, a conceptual data model, a logical data model, an entity relationship
188 model, an object class diagram or a database definition
189
- 190 **4.1.5**
191 **interoperability**
192 capability to communicate, execute programs, or transfer data among various functional units in a manner
193 that requires the user to have little or no knowledge of the unique characteristics of those units
- 194 [ISO/IEC 2382-1]
- 195 **4.1.6**
196 **metadata**
197 data which describes other data
- 198 [ISO/IEC 11179-1:2004, 3.2.16]
- 199 **4.1.7**
200 **metadata item**
201 instance of a **metadata object** (4.1.8)
- 202 [ISO/IEC 11179-3:2013, 3.2.75]
- 203 **4.1.8**
204 **metadata object**
205 object type defined by a **metamodel** (4.1.10)
- 206 [ISO/IEC 11179-3:2013, 3.2.76]
- 207 **4.1.9**
208 **metadata registry**
209 information system for registering **metadata** (4.1.6)
- 210 NOTE the associated information store or database is known as a metadata register
- 211 [ISO/IEC 11179-3:2013, 3.2.78]
- 212 **4.1.10**
213 **metamodel**
214 **model** (4.1.11) that explains a set of related **models** (4.1.11) by defining the language for expressing such
215 **models** (4.1.11)
- 216 [ISO 14813-5:2010, B.1.84]

- 217 **4.1.11**
218 **model**
219 representation of some aspect of a domain of interest using a normative **modelling facility** (4.1.17) and
220 **model constructs** (4.1.12)
- 221 NOTE models can be used to express a set of information requirements, processes, services, roles, goals or some
222 other aspect of a domain of interest
- 223 **4.1.12**
224 **model construct**
225 unit of notation to represent a **model** (4.1.11)
- 226 NOTE This is a more generic term for model element. Sometimes the term is used to include metadata, code and
227 object patterns rather than the notations of a particular modelling facility such as UML.
- 228 **4.1.13**
229 **model element**
230 element or component in a **model** (4.1.11)
- 231 NOTE Examples of model elements are representation of an entity type in an information model, representation of an
232 event in a process model, representation of a service operation in a service model, or representation of an actor in a
233 role and goal model.
- 234 **4.1.14**
235 **model information**
236 information that describes characteristics of a **model** (4.1.11) to be registered
- 237 NOTE In MFI, the model information about a model will be registered using instances of Registered_Item as specified
238 in ISO/IEC 11179-3
- 239 **4.1.15**
240 **model registry**
241 **registry** (4.1.23) where **models** (4.1.11) are registered
- 242 **4.1.16**
243 **model repository**
244 **repository** (4.1.24) where **models** (4.1.11) are stored
- 245 **4.1.17**
246 **modelling facility**
247 set of rules and notations for use when modelling
- 248 NOTE 1 UML is a typical example of a modelling facility
- 249 NOTE 2 May also be known as a modelling language
- 250 **4.1.18**
251 **modelling language**
252 language or notation that is used to model some aspect of a domain of interest
- 253 NOTE 1 UML is a typical example of a modelling language
- 254 NOTE 2 May also be known as a modelling facility

255 **4.1.19**
 256 **ontology**
 257 specification of concrete or abstract things, and the relationships among them, in a prescribed domain of
 258 knowledge

259 NOTE The specification should be computer processable

260 [ISO/IEC 19763-3:2010]

261 **4.1.20**
 262 **process**
 263 collection of related, structured activities or tasks that achieve a particular goal

264 **4.1.21**
 265 **process model**
 266 representation of a **process** (4.1.20), using a specific process **modelling language** (4.1.18)

267 **4.1.22**
 268 **registration**
 269 <generic> inclusion of a item in a **registry** (4.1.23)

270 <metadata registry> inclusion of a **metadata item** (4.1.7) in a **metadata registry** (4.1.9)

271 [ISO/IEC 11179-3:2013, 3.2.108]

272 NOTE 1 In ISO/IEC 19763 a metadata item is a model or a model element and a metadata registry is a model registry.

273 NOTE 2 Registration requires that a minimum set of administrative information about the metadata item (model) be
 274 specified, such that it becomes a registered item

275 **4.1.23**
 276 **registry**
 277 information system for **registration** (4.1.22)

278 [ISO/IEC 11179-3:2013, 3.2.113]

279 NOTE In ISO/IEC 19763, the registry is a Model Registry since the metadata items that are registered are models.
 280 This Model Registry uses facilities provided by a Metadata Registry as specified in ISO/IEC 11179-3

281 **4.1.24**
 282 **repository**
 283 place where, or receptacle in which, things are or may be stored

284 NOTE In MFI and MDR, a repository is recognized as a database that stores actual instances to conform to a
 285 particular metamodel or a particular set of metadata.

286 **4.1.25**
 287 **service**
 288 kind of web based application, which encapsulates one or more computing modules and can be accessed
 289 through a specified interface

290

334

335 **5 Purpose and objectives of MFI**

336 **5.1 Purpose of MFI**

337 MFI provides a set of specifications that allow the registration of models to facilitate interoperability among
338 systems or persons. In this context interoperability is interpreted in its broadest sense: the capability to
339 communicate, execute programs, or transfer data among various functional units in a manner that requires
340 the user to have little or no knowledge of the unique characteristics of those units (ISO/IEC 2382-1:1993).
341 The models that are registered may be ontologies, information models, process models, service models,
342 models of roles and goals or any other type of model specified within MFI.

343 Models are used widely within the information technology community to represent system requirements
344 and system specifications. These models can be expressed using a variety of notations or languages. An
345 information model may be expressed in any one of a number of entity-relationship notations, from the
346 simplicity of the original entity-relationship notation proposed by Dr Peter Chen through to the complexity of
347 Express-G, as a UML Class Diagram, or even as a set of SQL CREATE TABLE statements. Similarly,
348 process models may be expressed as BPMN models, as UML Activity Diagrams, or as a set of BPEL
349 statements.

350 The sharing of these models is essential if interoperability is to be achieved. If two systems are to
351 exchange information then not only must the formats in which the information is represented as data in
352 those systems be known but the semantics underpinning that data and the processes that the systems are
353 designed to support must also be unambiguously understood. If services are to be shared between
354 interoperating systems then the processes that these services execute, with their goals and the roles of the
355 people or organisations associated with these processes and services, also need to be unambiguously
356 understood.

357 The underlying purpose of MFI is to allow the sharing of these models. Each of the main parts of MFI
358 provides a specification, in the form of a metamodel, for a model registry where information about the
359 models, and the things, processes, etc that they are describing, can be registered. Once models have
360 been registered it is possible for the mappings between models, or parts of models, to also be registered.
361 In addition, because models are registered in a registry they can be discovered.

362 A metamodel in MFI is an information model that provides a conceptual view of the information that is
363 recorded when a model is registered. Each of these metamodels is expressed as a UML Class Diagram.

364 It is not sufficient to register a model in a registry. The registry must also be discoverable, and enabling this
365 discoverability of registries is also an important element of MFI.

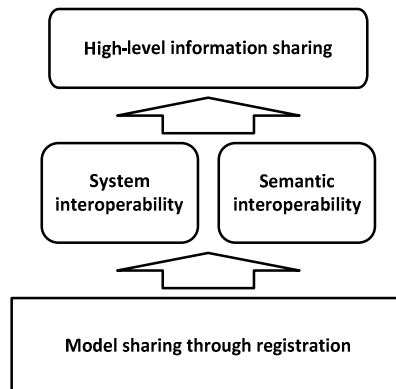

366 **5.2 Strengthening interoperability and integration capability**

367 **5.2.1 Introduction**

368 High-level information sharing is necessary to achieve the integration of data or services described above.
369 This relies upon the strengthening of the capabilities to discover models. This is underpinned by two types
370 of interoperability, as follows:

- 371 • System interoperability
- 372 • Semantic interoperability

373 This is illustrated in Figure 1 below.

374

375

Figure 1 – Two types of interoperability

376

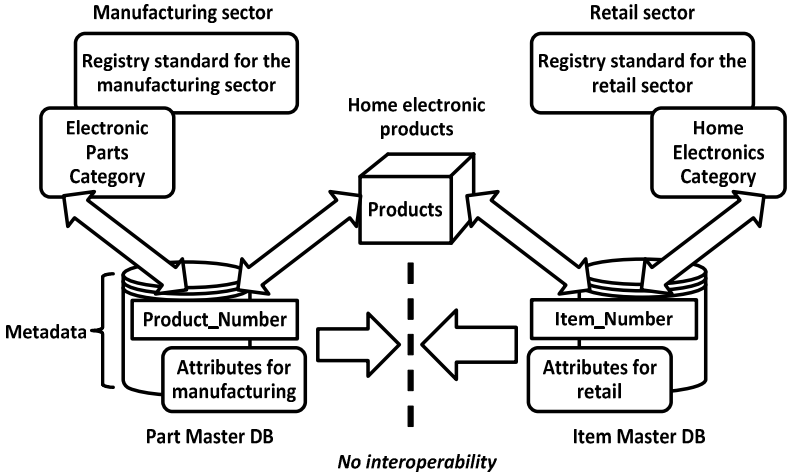

377 **5.2.2 System interoperability**

378 System interoperability in a heterogeneous network system requires the standardisation of the
 379 communication protocols to enable the lower level physical connection. It also requires the standardisation
 380 of both the message formats and the syntactic representation of the data to be exchanged. The syntactic
 381 representation of data is normally held as metadata.

382 Many de jure and de facto Standards Developing Organizations (SDO), such as ISO, IEC, UN, OMG and
 383 W3C, have developed and enforced many industry-specific metadata or registry standards. Examples exist
 384 in the e-business, healthcare, electronic parts, electronic documents and library areas, but most of these
 385 industry sector metadata or registry standards are incompatible with each other.

386 With this proliferation of standards it is not easy to share information across different industries or domains
 387 without any specific mapping or translation tools. This is made worse if the metadata is registered in
 388 different registries. For this reason it is almost impossible to have a global and dynamic supply chain that
 389 penetrates different industries across many countries.

390 For example, an electronics manufacturing company will have their own product database to handle the
 391 development, manufacture and sale of their products while the retailer will have their own item database
 392 which will be used to manage their stock and their purchases. Each database will have been developed
 393 individually, with each following the particular metadata standards, if any, that were specified by the
 394 industry consortium or some other SDO. In this situation it is almost impossible to achieve interoperability
 395 between the manufacturer's system and the retailer's system. Figure 2 illustrates this problem.

396

3

397

Figure 2 – Current problems with cross-industries interoperation

398
399
400

To overcome this problem there must be a mapping between the database structures of the two systems. To achieve this mapping the information models, and perhaps the process models, need to be understood and compared. The mappings themselves then need to be registered.

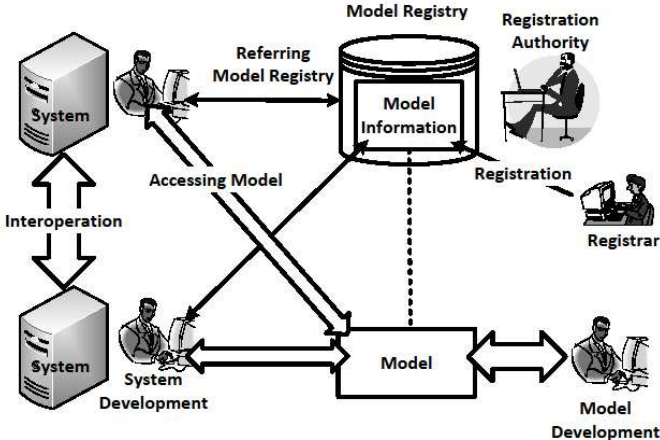

401
402
403
404
405
406

In software development, information models are used to capture and document the information requirements that should then lead to the specification of a database design. Each of these information models will be expressed using one of the many notations available, for example as a UML Class Diagram or as an IDEF1X model. Since many engineers are normally involved in any software development the sharing of models is common. Where this development involves collaborating engineers in different countries and languages, this model sharing must be supported by a specific platform or infrastructure.

407
408
409

In the model registry, MFI provides a basis for this model-sharing infrastructure. Model sharing can be made possible by registering these models in a model registry. This will make it easier to discover an appropriate model. See Figure 3 for an illustration of this concept.

410

411

412

Figure 3 – Basic concept of model sharing through a model registry

413

414 **5.2.3 Semantic interoperability**

415 Many terminology dictionaries are available, some on the internet. Some of these are generic dictionaries
 416 while the others each provide a set of technical terminologies in a specific domain, such as healthcare.

417 By enabling the registration of ontologies, where each ontology is a set of inter-related concept definitions
 418 within a specific domain of knowledge, MFI provides the ability to annotate each model construct so that
 419 data sharing and model sharing can be based on the semantic understanding of the model or the
 420 information represented by the model.

421 As well as aiding the understanding of the meaning of information, these facilities are also helpful in the
 422 definition of mapping rules between model constructs.

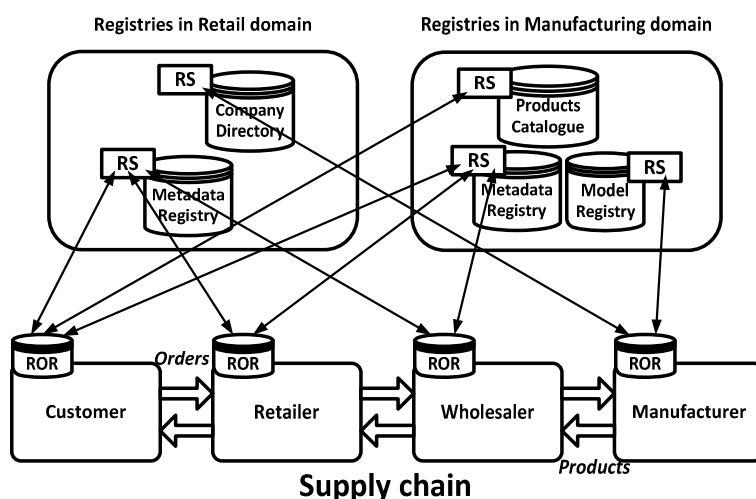

423

424 **5.3 Registry interoperability**

425 Another major purpose of MFI is to enable interoperability between registries. Many metadata registries or
 426 model registries are in existence, each designed to support industry-specific business domains in many
 427 different countries or territories. Most of these registries conform to industry-specific standards, such as for
 428 e-business, healthcare, or library operations. However, those standards themselves are incompatible with
 429 each other and they have been developed to meet the requirements specific to their own domains. It
 430 means that a single company or user who belongs to a particular domain experiences difficulties in
 431 accessing registries in other, different, domains.

432 To enable system interoperability, it is necessary to share information registered in different registries
 433 across different domains. To achieve this MFI specifies, using a metamodel, a set of small XML artefacts,
 434 called a Registry Summary (RS), which will record the nature of the registry and its content and also
 435 provide technical information to enable accessing the registry. The intention is that the RS should be
 436 attached to each registry.

437 Figure 4 below illustrates a typical example of the use of Registry Summaries. Each registry in a particular
 438 domain can make their Registry Summary publically available. Users in different domains, such as
 439 Manufacturing or Retailing, can then build their own dedicated registry that is a collection of Registry
 440 Summaries that are of interest to them. This special registry is called a Registry of Registries (ROR).

441

442

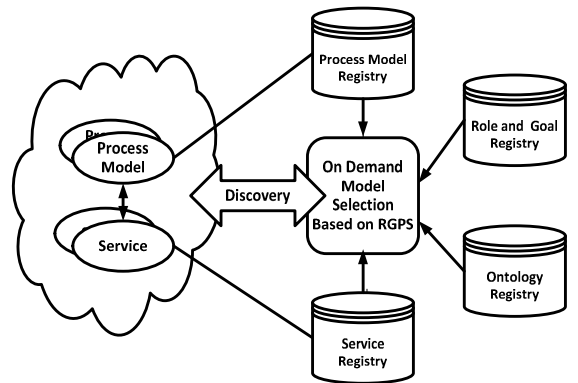

Figure 4 – Registry interoperability using RS and ROR

443

444 5.4 Model discovery

445 There is a need for the smart and efficient discovery and integration of information objects that are
 446 available over networks. This is made more urgent in the era of the internet, cloud computing and Linked
 447 Open Data (LOD), where there is a requirement for more sophisticated knowledge and service discovery.

448 MFI provides for this discovery through those parts that contribute to the Role, Goal, Process and Service
 449 (RGPS) facilities: the metamodel for process model registration, the metamodel for service registration,
 450 and the metamodel for role and goal registration. The use of these parts is brought together in the
 451 Technical Report that explains the on demand model selection based on RGPS, as illustrated in Figure 5.

452

453 **Figure 5 – Discovering services and processes based on RGPS**

454

455 6 Model registration

456 6.1 Basic idea of the MFI metamodels

457 A metamodel is a model that is used to explain a set of related models by defining the language that is
 458 used for expressing such models. In MFI the metamodels specified in the different parts define the set of
 459 concepts described in the models under consideration that are important for interoperability and, therefore,
 460 need to be registered.

461 In MFI all of the metamodels are specified as UML Class Diagrams, which means that all of the MFI
 462 metamodels are described using the UML metamodel.

463 However, UML is not the only set of notations used for domain modelling. Other languages, such as
 464 IDEF1X for information modelling and BPMN for business process modelling, are often used. All of the MFI
 465 metamodels, therefore, are not designed for a specific domain modelling language but are able to
 466 accommodate generic concepts covered by the type of model concerned (ontologies, information
 467 modelling, process modelling, etc).

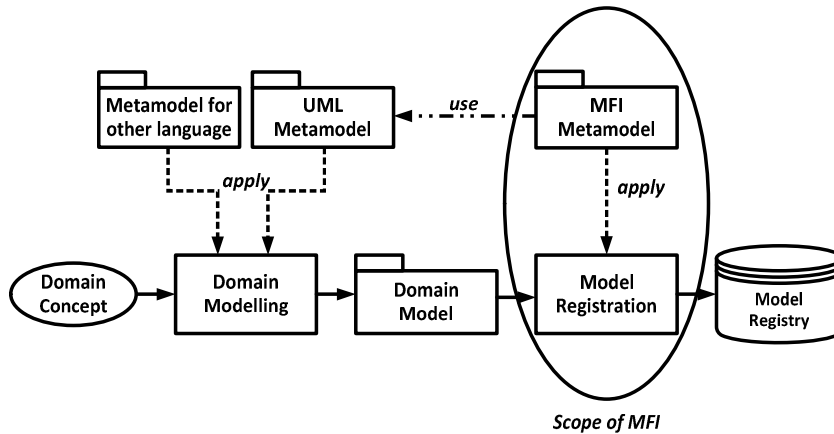

Figure 6 – MFI metamodels and the UML metamodel

6.2 Basic concept of model registration

MFI is a set of metamodels specifying the structure of registries that may be used to register various types of models. The use of these MFI metamodels makes the model registration process easier. They also enable consistency in the information to be registered about the models.

Figure 7 shows the basic concept of the model registration. The MFI metamodels provide a registrar with a consistent view of model information that needs to be registered.

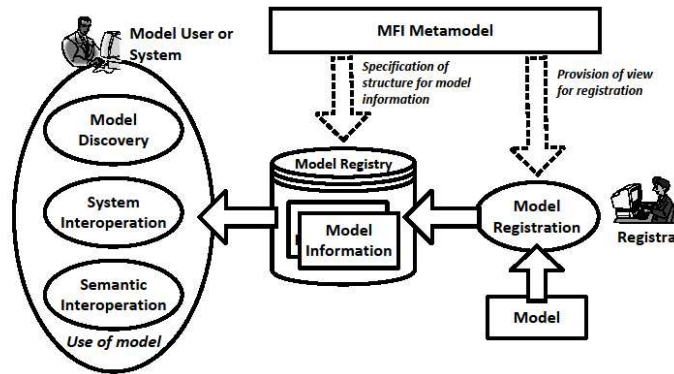

Figure 7 – Basic concept of MFI registration

One of the MFI metamodels is a core model that provides common features that are used by all the other parts. The model constructs in the metamodels in the other parts are all specialisations of model constructs defined in the core model. The metamodels for the other parts provide details of the information to be registered for:

- ontologies
- information models
- process models
- services

- 487 • role and goal models
- 488 • form descriptions

489 MFI does not specify any implementation requirements for a registry. Each metamodel only specifies the
 490 information that may be registered about a model. A registry does not store the actual model instance in its
 491 database; only the model information is stored.

492 The model information stored in a registry provides information about:

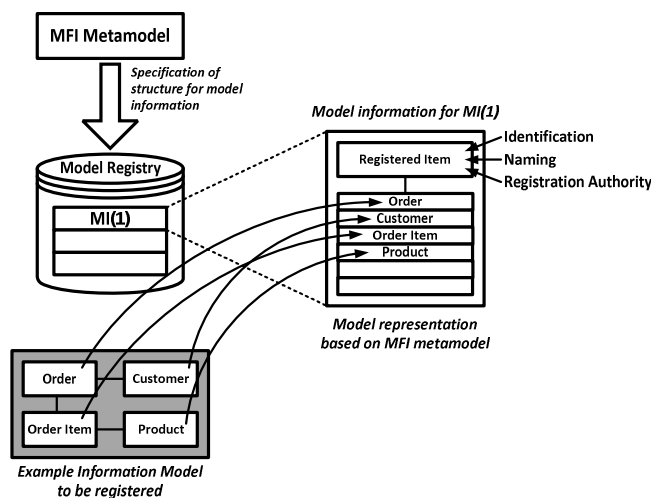

- 493 • where the model exists, who is the owner, and when it is registered,
- 494 • what model elements are included in the model, and
- 495 • what are relationships between these model elements.

496 MFI assumes that the actual models to be shared are stored outside of MFI. This storage may be
 497 electronic in a model repository or the models may be held as documents.

498 An MFI registry uses the registration facilities that are specified in the MDR Metamodel. As such, for each
 499 model the following information may be recorded:

- 500 • details of the registration authority, including the registrar.
- 501 • the date of the registration.
- 502 • the submission status.
- 503 • the ownership of the model.
- 504 • the context of the model.
- 505 • the elements within the model.

506 In terms of the MDR Metamodel, the registered model becomes a registered item, as shown in Figure 8.

507

508 **Figure 8 – Relationship between a model and its associated model information**

509

510 **7 MFI architecture**

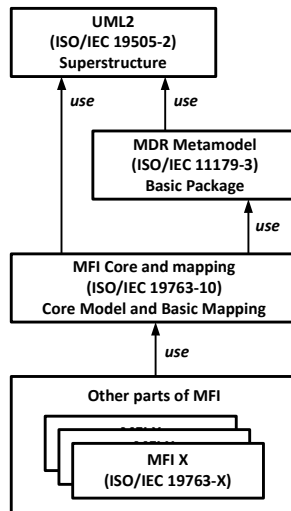

511 **7.1 The overall structure of MFI**

512 This section specifies the architecture of MFI. All future developments of extra parts of MFI must adopt this
513 architecture.

514 The MFI family of standards consists of a number of parts, each of which (other than this part and any
515 technical reports) specifies a metamodel. Most of these metamodels provide for the registration of a
516 particular type of model. One part (Part 10) provides common facilities for the other parts: a core model
517 and basic mapping facilities.

518 In order to achieve the purpose set out in Clause 5 the MFI family of standards needs to be tightly
519 harmonised with the MDR family of standards. This is because metadata is needed to define the model
520 information that is to be registered in the MFI registries. MFI uses the registration procedure specified in
521 MDR Registration.

522 MFI can be considered to be an extension of MDR. Figure 9 shows the basic overall structure of the MFI
523 standard, including its relationship to MDR and UML.

524

525 **Figure 9 – Overall structure of MFI and its relationships to MDR and UML**

526

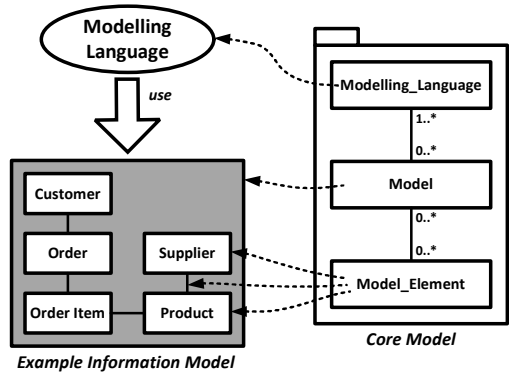

527 **7.2 A common modelling facility for MFI**

528 To maintain consistency between the parts of the MFI family of standards, one of the parts (Part 10)
529 provides common modelling facilities in addition to facilities to map models together.

530 Figure 10 shows the core model concept. Central to the core model are three metaclasses:

- 531 • Modelling_Language,
- 532 • Model, and
- 533 • Model_Element.

534 The inclusion of Modelling_Language allows models expressed in any modelling language to be registered.

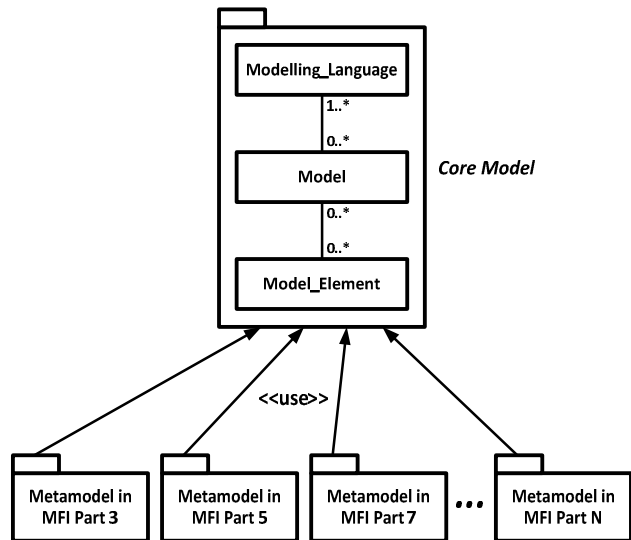

535

536

Figure 10 – Basic concept of the core model

537
538
539

The metaclasses in the metamodels specified in the other parts are all specialisations of one of the metaclasses in the core model, as shown in Figure 11. As new parts are developed they will follow this structure, thus ensuring that the architecture is maintained.

540

542

Annex A
(informative)
Internal structure of MFI

543
544
545
546

547 The MFI family of standards is still evolving but this Annex describes the parts that are planned at the time
548 of publication of this framework.

Note: The Role-Goal-Process-Service (RGPS) Family forms a set of standards that together facilitate the discovery of services

549

550

551

MDR

553 In order to maintain consistency in the registration of objects, such as models or model elements, all parts
554 of MFI share the same administrative information that is defined in the basic package of ISO/IEC11179-3.
555 This enables MFI registries to make use of the common facilities provided by metadata registries. Thus, a
556 model or a model element may be registered as one or more of the types specified in ISO/IEC 11179-3, ie:

- 557 • an Identified_Item
- 558 • a Registered_Item
- 559 • an Administered_Item
- 560 • an Attached_Item
- 561 • a Designatable_Item
- 562 • a Classifiable_Item

MFI Part 1: Framework

564 Part 1 (this part) describes the concepts, including registration, and the overall architecture of the standard
565 that is to be applied in the development of the individual metamodels specified in the other parts.

MFI Part 10: Core model and basic mapping

567 Part 10 specifies the core model that provides the framework for all other metamodels specified in the
568 other parts. It also provides facilities to enable individual models and model elements to be annotated with
569 constructs from ontologies and facilities to enable the mapping of models to other models.

570 MFI Part 3: Metamodel for ontology registration

571 Part 3 specifies a metamodel that provides for the registration of administrative information about
572 ontologies. These ontologies may be used to annotate elements of other models.

573 MFI Part 5: Metamodel for process model registration

574 Part 5 specifies a metamodel that provides for the registration of administrative information about different
575 kinds of process models. These process models may describe the processes supported by a system or
576 may support the discovery of services through RGPS.

577 MFI Part 6: Registry summary

578 Part 6 specifies a metamodel of the registry summary information that may be added to any type of registry.
579 This summary information can be collected together into a Registry of Registries (ROR).

580 MFI Part 7: Metamodel for service registration

581 Part 7 specifies a metamodel for the registration of administrative information about services. The main
582 focus of this part is on web services but the metamodel can be used to register any service that is
583 supported by a set of processes.

584 MFI Part 8: Metamodel for role and goal registration

585 Part 8 specifies a metamodel for the registration of administrative information about the roles and goals
586 that are associated with processes and services.

587 MFI Part 9: On demand model selection based on RGPS (Technical Report)

588 Part 9 is a technical report that explains how a registry, or a collection of interconnected registries, that is
589 based the metamodels specified in Parts, 5, 7 and 8 may be used together to discover models, particularly
590 models that represent services.

591 MFI Part 12: Metamodel for information model registration

592 Part 12 specifies a metamodel for the registration of administrative information about information models,
593 models that describe the information recorded in a system. These may be entity-relationship models, UML
594 Class Diagrams or SQL table definitions.

595 MFI Part 13: Metamodel for form registration

596 Part 13 specifies a metamodel for the registration of administrative information about the structure of forms,
597 such as electronic health records or other legal or official forms.

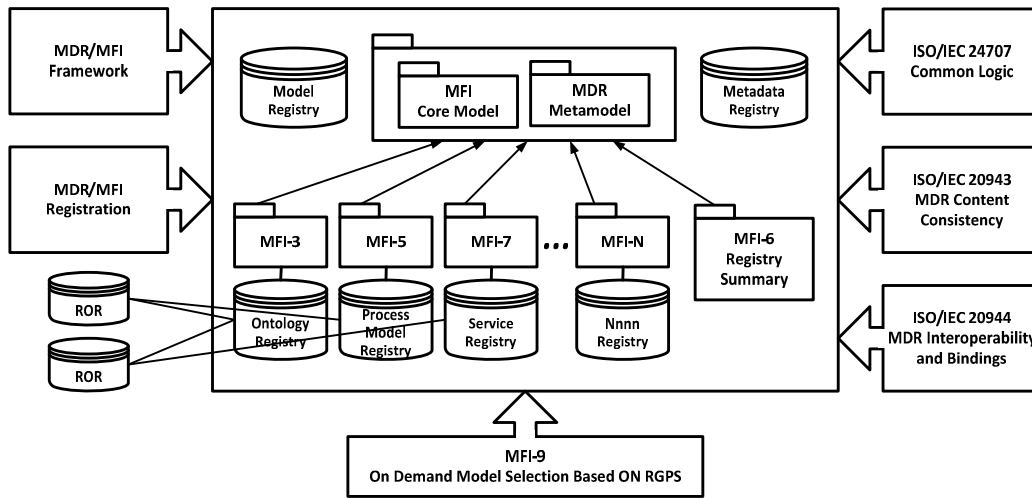

598

Annex B
(informative)
Future harmonised structure for MFI and MDR

599
600
601
602

603 MFI relies heavily on the common facilities provided by the MDR Metamodel. It is envisaged that at some
604 stage in the future there should be even closer harmonisation of the MFI and MDR standards, the
605 ISO/IEC19763 family of standards, the ISO/IEC11179 family of standards and their associated standards.
606 This closer harmonisation will enable more effective and efficient use of both metadata and models.

607 Figure B.1 illustrates the final target of the harmonisation on MFI and MDR.

608

609
